Abstract

Purpose: To compare the levels of gene expression for enzymes involved in production and elimination of reactive oxygen/nitrogen species (ROS/RNS) in normal human corneal cells (NL cells) with those in human corneal cells with keratoconus (KC cells) *in vitro*.

Methods: Primary NL and KC stromal fibroblast cultures were incubated with apocynin (an inhibitor of NADPH oxidase) or N-nitro-L-arginine (N-LLA; an inhibitor of nitric oxide synthase). ROS/RNS levels were measured using an H₂DCFDA fluorescent assay. The RT2 Profiler™ PCR Array for Oxidative Stress and Antioxidant Defense was used for initial screening of the NL and KC cultures. Transcription levels for genes related to production or elimination of ROS/RNS were analyzed using quantitative PCR. Immunohistochemistry was performed on 10 intact human corneas using antibodies against SCARA3 and CPSF3.

Results: Array screening of 84 antioxidant-related genes identified 12 genes that were differentially expressed between NL and KC cultures. Compared with NL cells, quantitative PCR showed that KC cells had decreased expression of antioxidant genes SCARA3 isoform 2 (0.59-fold, $P = 0.02$) and FOXM1 isoform 1 (0.61-fold, $P = 0.03$). KC cells also had downregulation of the antioxidant genes SOD1 (0.4-fold, $P = 0.0001$) and SOD3 (0.37-fold, $P = 0.02$) but increased expression of SOD2 (3.3-fold, $P < 0.0001$), PRDX6 (1.47-fold, $P = 0.01$), and CPSF3 (1.44-fold, $P = 0.02$).

Conclusion: The difference in expression of antioxidant enzymes between KC and NL suggests that the oxidative stress imbalances found in KC are caused by defects in ROS/RNS removal rather than increased ROS/RNS production.

INTRODUCTION

Keratoconus (KC) is a progressive corneal thinning disorder that causes irregular astigmatism and reduced vision. It affects approximately 1 in 375 individuals and is an indication for corneal transplant surgery.^[1-4] In about 6%–10% of cases, KC reportedly has an autosomal dominant inheritance pattern with incomplete penetrance.^[5-7] The mechanism(s) causing KC are not known but are thought to involve a combination of genetic and environmental factors. The cornea is constantly exposed to ultraviolet light, which is a common source of free radicals and reactive oxygen/nitrogen species (ROS/RNS). Numerous molecular and biochemical studies have reported elevated levels of oxidative damage in corneas, cultured cells, and tears from eyes with KC.^[8-11] Oxidative stress causes tissue degradation,^[12] which may contribute to stromal thinning and loss of Bowman's layer in a cornea with KC.^[1,2] *Ex vivo* corneas with KC contain biochemical markers for peroxynitrites and malondialdehydes, which are cytotoxic byproducts of the nitric oxide and lipid peroxidation pathways, respectively.^[8] Peroxynitrites (ONOO⁻), formed by the combination of superoxides (O^{•-}) with nitric oxides [Figure 1], can damage DNA, proteins, and lipids. An increase in oxidative stress is associated with inherited and acquired mitochondrial dysfunction.^[13] Pathak et al identified mutations in complex 1 genes that are pathogenic and exclusive to KC.^[14] Corneas with KC also have elevated levels of mitochondrial DNA (mtDNA) damage along with decreased levels of mitochondrial-encoded cytochrome c oxidase (complex IV subunit 1, MTCO1), consistent with mitochondrial dysfunction.^[15]

Evidence of the oxidative stress seen in corneas with KC has also been found in cultured KC cells. KC fibroblasts have higher levels of ROS/RNS and caspase-3/7 activity *in vitro*, along with altered levels of cytochrome c oxidase (complex IV subunit II, MTCO2), a decreased mitochondrial membrane potential, degraded mtDNA, and increased activation of the caspase-9 mitochondrial pathway.^[9,16] There is normally a balance between the amounts of ROS and RNS produced and eliminated with antioxidants, but this balance is altered in patients with KC, even on a systemic level.^[17,18]

The present study was designed to evaluate the key components involved in the balance of oxidative stress elements. On the production side, we measured gene expression levels for multiple subunits of NADPH oxidase, an enzyme responsible for production of superoxides, and for inducible nitric oxide synthase (NOS2), which produces nitric oxide [Figure 1]. On the elimination side, we measured the gene expression levels for nine antioxidant enzymes, along with SCARA3, which is a major ROS/RNS scavenger, and FOXM1, a transcription factor for antioxidant genes. Our findings suggest that oxidative stress likely results from a disruption of the elimination pathways rather than overproduction of ROS or RNS in corneas with KC. This finding may provide

Figure 1. Schematic diagram of pathways involved in production and elimination of ROS/RNS. important guidance for future therapeutic reduction of oxidative damage in corneas with KC.

METHODS

Corneal Fibroblast Cultures

Six normal corneas from donors aged 24–59 (mean 40.2) years were received within 24 hours post mortem from the National Disease Research Interchange (Philadelphia, PA). Five corneas with KC from patients aged 25–46 (mean 34.8) years were received in McCarey-Kaufman medium on ice within 24 hours of penetrating keratoplasty. The donors and patients were matched for age and sex. The study was performed according to the tenets of the Declaration of Helsinki for research involving human subjects and a written informed consent was obtained from all study participants.

The diagnosis of KC was based on more than one of the following criteria: Munson's sign, Rizzuti phenomenon, slit-lamp findings (e.g., stromal thinning, Vogt's striae, Fleischer ring, and epithelial or subepithelial scarring); retroillumination signs (e.g., oil droplet sign, scissoring on retinoscopy); photokeratotomy signs (e.g., infero-temporal, inferior, or central compression of mires); videokeratography signs (e.g., localized increased surface power and/or inferior-superior dioptric asymmetry), and corneal topography. NL and KC stromal cells were isolated and cultured as described elsewhere.^[19] When corneal stromal cells are cultured in 10% fetal bovine serum, they differentiate into fibroblasts.^[20,21] Our corneal cells stained with vimentin (a marker for fibroblasts) but did not stain with alpha smooth muscle actin (a marker for myofibroblasts). The morphology was consistent with fibroblasts and not corneal keratocytes.

Inhibitor Studies

Third passage fibroblasts were used for the individual experiments ($n = 4$). Cells were plated overnight in phenol

red-free minimum essential medium with 10% fetal bovine serum (Omega Scientific Inc., Tarzana, CA). Some cells were cultured for 2 hours with either apocynin (30 μ M, an inhibitor of NADPH oxidase [Sigma-Aldrich, St Louis, MO]) or N-nitro-L-arginine (N-LLA; 100 μ M, an irreversible inhibitor of constitutive nitric oxide synthase [NOS]) and a reversible inhibitor of inducible NOS (iNOS; Sigma-Aldrich). ROS/RNS levels were measured using a fluorescent dye (2',7'-dichlorodihydrofluorescein diacetate) assay (Invitrogen, Waltham, MA) as described previously.^[9] The statistical analyses were performed using the unpaired *t*-test.

Gene Expression Array Studies

The NL (*n* = 2) and KC (*n* = 2) corneal cell cultures were analyzed using the RT2 Profiler™ PCR Array for Oxidative Stress and Antioxidant Defense (SABiosciences, Frederick, MD). RNA was isolated using the RNeasy Mini Kit (Qiagen, Inc., Valencia, CA) following the manufacturer's protocol. For the complementary DNA synthesis, 1 μ g of RNA was used for the RT2 First Strand Kit (SABiosciences) according to the manufacturer's protocol. The complementary DNA was then processed at the UCLA Sequencing Core Facility (Los Angeles, CA). The analyses were performed using the SA Biosciences RT² array analysis software.

Quantitative PCR Analyses

After our initial screen using the Oxidative Stress and Antioxidant Defense array, we performed quantitative polymerase chain reaction (Q-PCR) on enzymes associated with production and elimination of ROS/RNS in the NL (*n* = 6) and KC (*n* = 5) cultures. The NADPH oxidase family consists of 7 isoforms, each consisting of a core catalytic subunit (NOX and DUOX) with up to 5 regulatory subunits [Figure 2]: *p22phox* (CYBA), *p67phox* (NCF2), and *p47phox* (NCF1).^[22] Gene expression analyses were also performed for antioxidant enzymes responsible for ROS/RNS elimination, i.e., CAT, GPX3, PRDX3, PRDX4, PRDX6, SOD1, SOD2, SOD3, and USP36. Isoforms for SCARA3, a ROS scavenger, were evaluated along with CPSF3, a processing endonuclease associated with SCARA3. The expression levels for FOXM1 (a transcription factor for antioxidant enzymes) were measured. The primers for the total FOXM1 and isoform 1 FOXM1 were available but not for isoforms 2 or 3. Q-PCR primers were purchased from Qiagen.

RNA was extracted from the pellets of the cultured cells using the RNeasy Mini Kit (Qiagen) according to the manufacturer's instructions and quantified on a Nanodrop 2000. Next, 500 ng of RNA was reverse-transcribed into complementary DNA using the QuantiTect Reverse Transcription

Figure 2. Schematic diagram of subunits associated with the NADPH oxidase enzyme. The *p22phox* subunit is utilized by NOX1-NOX4 but not the NOX5, DUOX1, or DUOX2 enzymes. The *p47phox* subunit is utilized by NOX1 and NOX2. The *p67phox* and *p40phox* subunits are only associated with NOX2.

Kit (Qiagen). The Q-PCR was carried out with the QuantiFast SYBR Green PCR Kit (Qiagen) according to the manufacturer's protocol, using β 2-microglobulin primers (forward, CTCGCGCTACTCTCTCTTTCTG; reverse, GCTTACATGTCTCGATCCCACTT) and TATA box binding protein (Qiagen) as the housekeeping genes. The data were analyzed using GraphPad Prism 5 (GraphPad Software Inc., La Jolla, CA).

Immunohistochemistry Studies

Ten NL corneas and 10 KC corneas were examined by immunohistochemistry using the rabbit polyclonal antibody to Scavenger Receptor Class A, Member 3 protein (SCARA3, GeneTex, Irvine, CA) or the rabbit polyclonal antibody to Cleave and Polyadenyl Specific Factor 3 (CPSF3, GeneTex). The secondary antibody was the Alexa Fluor® 555 goat anti-rabbit IgG (H + L; Invitrogen). The corneas were embedded in Tissue-Tek OCT compound (Sakura Finetek USA Inc., Torrance, CA) prior to freezing in liquid nitrogen. Tissue sections were cut, mounted onto microscope slides, and stored at -80°C . The tissues were counterstained with DAPI (Invitrogen). Slide images were captured with a Nikon E600 fluorescent microscope and MetaMorph software. The epithelial and stromal staining patterns were examined using a subjective 0–4+ scoring system (0, little or no staining; 1+, weak staining; 2+, moderate staining; 3+, intense staining; and 4+, very intense staining).

Statistical Analysis

The statistical analysis was performed using Simple Interactive Statistical Analysis (SISA) Internet software (Quantitative Skills, Amsterdam, the Netherlands) and the Student's *t*-test using GraphPad Prism software.

RESULTS

Pathways for Production of ROS/RNS

Studies were performed to determine if the ROS/RNS levels in NL and KC cultures could be altered by pre-treatment with apocynin, an inhibitor of NADPH oxidase, or N-LLA, an inhibitor of NOS. The KC cultures ($n = 5$) had a 1.8-fold increase in ROS/RNS levels compared to untreated NL cultures ($P = 0.004$), which could not be reversed by pre-treatment with apocynin ($P = 0.9$) or N-LLA ($P = 0.8$; Figure 3). These inhibitor studies indicated that the higher ROS/RNS levels found in KC cultures could not be reversed by blocking the NADPH oxidase or NOS pathways. The mechanism of action of apocynin involves inhibition of the association of the NADPH oxidase *p47phox* subunit with the membrane-bound heterodimer^[22] and we reasoned that perhaps the *p47phox* subunit was diminished in human corneal fibroblasts. The gene expression patterns of various NADPH oxidase subunits were examined to ensure that our findings were not caused by reduced expression of the *p47phox* subunit in cultured KC cells. The *p47phox* subunit is associated with *NOX1* and *NOX2* but not with *NOX3*, *NOX4*, *NOX5*, *DUOX1*, or *DUOX2*. In addition to the *p47phox* subunit, the gene expression patterns of *p22phox*, which is associated with *NOX1-NOX4*, *DUOX1* and *DUOX2*, were also analyzed. The mRNA expression of *p67phox* was measured because it is associated with *NOX2* and expressed in human corneal cells.^[23] Table 1 shows that the expression patterns for *p47phox*, *p67phox*, *p22phox*, *DUOX1*, *DUOX2*, and *NOS2* were not changed in KC cells when compared with NL cells.

Figure 3. KC cells have significantly elevated ROS/RNS levels compared with NL cells (1.8-fold, $***P = 0.004$). Pretreatment for 2 hours with 30 μ M apocynin (an inhibitor of NADPH oxidase) or 100 μ M N-nitro-L-arginine (an inhibitor of nitric oxide synthase) did not decrease the ROS/RNS levels to those in NL cells. KC, keratoconus; NL, normal; RNS, reactive nitrogen species; ROS, reactive oxygen species.

Pathways for Elimination of ROS/RNS

Antioxidant genes associated with elimination of ROS/RNS were altered in KC cultures when compared with NL cultures [Table 2]. The KC cells had a significant reduction in gene expression for two antioxidant enzymes, i.e., *SOD1* (NM_000454, $P = 0.0001$) and *SOD3* (NM_003102, $P = 0.02$), while *SOD2* (NM_00636, NM_001024465, $P = 0.0001$) and *PRDX6* (NM_004905, $P = 0.01$) had increased expression. The levels for *USP36*, *CAT*, *GPX3*, and *PRDX4* were similar in NL cells and KC cells.

SCARA3 (also known as CSR1 and MSR1) is a ROS scavenger that protects cells against ultraviolet light. The gene expression levels for total SCARA3 (NM_016240, NM_182826) and the full-length isoform, variant 1 (NM_016240), were not significantly changed in comparison with NL cells [Table 3]. The shorter SCARA3 variant 2 (NM_182826, see lower panel) showed a 0.59-fold decrease ($P = 0.02$) in the KC cells when compared with the NL cells. The gene expression levels for *CPSF3*, a pre-mRNA 3-prime end-processing endonuclease that is closely associated with SCARA3,^[24] was significantly increased in the KC cells (1.44-fold, $P = 0.0017$).

Given that SCARA3 and CPSF3 have not been previously identified in human corneas, immunohistochemistry was performed on NL and KC corneas with SCARA3-specific and CPSF3-specific antibodies [Figure 4]. The SCARA3 and CPSF3 proteins were present in stromal cells in both NL and KC corneas (box inserts). Surprisingly, we found the greatest staining for the SCARA3 protein in the NL epithelium (+4 in 4 samples and +3 in 6 samples) with slightly less in the KC epithelial cells (+3 in 7 samples and +2 in 3 samples).

Figure 4. Immunohistochemistry shows SCARA3 staining in NL and KC corneas. The epithelial cells have a distribution of SCARA3 throughout the cytoplasm of the NL and KC corneas. The CPSF3 protein staining is found within the cytoplasm of the epithelial cells and stromal cells. No staining was observed when only the secondary antibody (IgG) was used on the tissue sections (negative control). NL, normal; KC, keratoconus; E, epithelial; S, stroma.

Expression for the *FOXM1* isoform 1, an important transcription factor for antioxidant genes, was significantly decreased in KC cells [Table 4]. In these cells, expression of the *FOXM1* isoform variant 1 (NM_202002) was decreased by 0.61-fold ($P = 0.03$). This full-length *FOXM1* isoform has 10 exons and contains 3641 bp. Exon 9 is missing in isoform variant 2 of *FOXM1* (NM_021953), while both exons 6 and 9 are missing in isoform variant 3 of *FOXM1* (NM_202003).

DISCUSSION

Pathways for Production of ROS/RNS

The major source of superoxides in human corneal stromal fibroblasts has been reported to be through the NADPH oxidase pathway.^[23] Our results support this finding and show that NL and KC human corneal fibroblasts have similar expression levels of *p22phox*, *p47phox*, and *p67phox* NADPH oxidase subunits.

Analyses of other genes in the NADPH oxidase family showed expression of *DUOX1* and *DUOX2* in human NL and KC corneal cells. Unlike other NADPH oxidase family members that produce superoxides that are then converted into hydrogen peroxides, the *DUOX1* and *DUOX2* oxidases are NADPH oxidase homologues that directly produce hydrogen peroxide.^[25,26] Although *DUOX1* and *DUOX2* proteins have been previously reported in thyroid cells, epithelial cells in the airway, prostate cells, salivary glands, and gastrointestinal cells,^[27] their roles in human corneal cells are unclear at this time and warrant further investigation. No differences in any of the NADPH oxidase enzymes were found between NL and KC cells, so we concluded that it was unlikely that the elevated ROS/RNS levels in KC cells were the result of increased NADPH oxidase-related production.

While Buddi et al observed that KC stromal cells show increased accumulation of iNOS protein,^[8] our KC and NL cell cultures showed similar expression levels of iNOS. Peroxynitrite and nitric oxide are toxic to corneal cells due to inducing gelatinase/matrix metalloproteinase (MMP)-2 activity and diminishing TIMP-1 levels, reflecting a direct relationship between elevated oxidative stress and tissue degradation.^[12,28] Activation of MMPs, such as MMP-2 and prooxidase, is important in the degradation and remodeling of collagen in the corneal stroma.^[29] Oxidative stress-induced activation of MMPs and abnormal enzyme levels

contribute to the stromal thinning and loss of Bowman's layer which are characteristics of KC.

Pathways for Elimination of ROS/RNS

An alternative mechanism for accumulation of ROS/RNS is decreased removal of the oxidants once they are formed. Screening of 84 antioxidant-related genes showed 12 genes that were differentially expressed between the NL and KC cultures. These were further analyzed with Q-PCR and showed depressed expression levels of *SOD1* and *SOD3*, both of which are critical antioxidant enzymes that convert superoxide to hydrogen peroxide. The *SOD1* gene (cytosolic copper-zinc SOD) is on chromosome 21 and has been linked to KC through a deletion within intron 2 that segregates in affected family members.^[30,31] This deletion was recently reported in subjects with sporadic KC,^[32] contrasting with other studies that did not find this defect in association with KC.^[33] The enzyme activity for *SOD3* (extracellular matrix SOD) was also lower in corneas with KC.^[34] *SOD1*-null and *SOD3*-null mouse models showed elevated superoxide levels in the corneas, which could contribute to oxidative damage.^[35] Furthermore, it is reasonable to propose that lower antioxidant enzyme levels in KC cells may lead to increased accumulation of ROS/RNS, as seen in our cultured KC cells.

SOD2 is a tetrameric enzyme that contains manganese and is located in the matrix of the mitochondria. Previously, it has been shown in an American population^[15] and in a Chinese population^[36] that corneas with KC have

more mtDNA damage than normal corneas. While the Chinese study found that expression of SOD2 was lower in corneas with KC than in normal corneas,^[36] it was 3.3-fold higher in KC cells than in NL cells in the present study. Interestingly, Ortak et al reported that subjects with KC had higher total plasma SOD levels than subjects without KC.^[37] These conflicting findings point to a need for additional studies to explain this discrepancy and whether increased mtDNA damage has stimulating or inhibiting effects on transcription of SOD2. Based on the results of this study and other previous studies, the elimination patterns for ROS/RNS are significantly altered in subjects with KC and in KC cell cultures, which can contribute to oxidative damage and enzymatic matrix degradation, which are key features in corneas with KC.

PRDX6 is a redox regulation enzyme that reduces levels of hydrogen peroxide and phospholipid hydroperoxides and protects cells against oxidative injury and inflammation.^[38] We found that expression levels of PRDX6 were higher in KC cells than in NL cells. Differential expression of peroxiredoxin isoforms has been associated with Fuchs' endothelial dystrophy.^[39] In human ovarian cancer cells, its overexpression reduces ROS levels and caspase activity and stops cells from undergoing apoptosis.^[40] Given the altered levels of numerous antioxidant enzymes, corneas with KC would have altered levels of superoxides and hydrogen peroxide, which could dramatically change cell signaling cascades, cytokine levels, and degradative enzyme activity.

The KC cells showed a significant decrease in isoform 2 SCARA3 gene expression when compared to the NL cells. SCARA3, located at chromosome 8p21, is a critical scavenger protein that depletes ROS and thereby protects

cells from oxidative stress. When in the unstressed state, SCARA3 is localized to the Golgi apparatus in the endoplasmic reticulum; however, upon exposure to hydrogen peroxide, SCARA3 scavenger proteins diffuse into the cytoplasm^[41] where they transport free radicals to lysosomes for processing and removal. SCARA3 has two alternatively spliced variants. The shorter SCARA3 isoform (CSR2, NM_182826), which is present at lower levels in KC cells, lacks the collagen-like domain, has exon 6 shortened to 258 bp with a shorter C-terminal tail, and codes for a 466-amino acid protein. SCARA3/CSR1 isoform 1 (NM_01240) contains 3631 bp with a full-size exon 6 and a long poly(A)' tail. The predicted 606-amino acid protein has a leucine zipper motif that overlaps at its N-terminus with a transmembrane domain and two collagen-like domains. The protein has numerous phosphorylation and N-glycosylation sites, a putative heme-binding site, and microbody-targeting signals.

Normal skin fibroblasts exposed to ultraviolet light or hydrogen peroxide show significantly elevated CSR/SCARA3 expression, which can be reversed by pretreatment with antioxidant compounds.^[41] Cells overexpressing CSR1/SCARA3 or CSR2/SCARA3 have increased resistance to damage caused by ultraviolet light.^[41] This feature is an important property for corneal cells that are constantly being exposed to sunlight. The collagenous domains of the full-length CSR1/SCARA3 isoform can bind lipids and other negatively charged molecules, such as fibrinogen and laminins. The shorter splice variant CSR2/SCARA3 lacks these collagenous domains, which could contribute to functional behavior different from that of the full-length CSR1/SCARA3. The significance of decreased SCARA3 in KC cells is

not known, but one could speculate that lower levels of this important scavenger would result in elevated levels of ROS/RNS and the increased apoptosis of anterior stromal cells found in corneas with KC.^[42] Another mechanism by which CSR/SCARA3 may affect KC cells is via its association with CPSF3, an enzyme necessary for polyadenylation of RNA.^[43,44] The CPSF3 protein is a critical pre-mRNA 3-prime end-processing endonuclease that converts heteronuclear RNA to mRNA.^[24] Increased levels of CPSF3, as seen in KC cells, potentially alter patterns of cell death and other cell functions. Zhu et al showed that the C-terminus of CSR1/SCARA3 interacts with CPSF3, which is then translocated from its location in the nucleus to a cytosolic distribution.^[45] In KC cells, there were significantly higher expression levels of SCARA3 isoform 2, which has a shortened C-terminus. This altered expression could potentially affect pre-mRNA processing within the cells and might account for the numerous altered genes reportedly found in corneas with KC.^[46-48]

Altered Gene Regulation

Our data, along with those of others, suggest that KC cells have abnormalities in multiple antioxidant pathways that contributes to the pathology of KC. The present study showed that KC cells had a 0.61-fold decline in FOXM1 isoform 1 (NM_202002). FOXM1 is in the Forkhead Box transcription factor family that has a conserved winged helix DNA domain and is a transcription factor for antioxidant enzymes. It has dual functions involving cell cycle progression and also tumor cell migration/invasion. FOXM1 promotes cell growth by regulating genes involved in DNA repair, mitosis, chromatin assembly, and protein metabolism.^[49,50] In tumors, high FOXM1B expression levels are correlated with a poor prognosis.^[49] FOXM1 plays an essential role in regulation of oxidative stress^[51] and modulates intracellular ROS levels by upregulating expression levels of antioxidant genes that protect cells from oxidative damage. Fibroblasts with FOXM1 silenced by siRNA transfection become significantly less viable after treatment with hydrogen peroxide.^[51] Low levels of FOXM1 in KC cells result in diminished expression of antioxidant genes and potential accumulation of ROS/RNS within these cells. This would render KC cells more susceptible to oxidative damage and less able to survive exposure to stressors, such as hydrogen peroxide or low pH.^[9,16]

In summary, our findings suggest that the elevated ROS/RNS levels found in KC cells are more likely to reflect less efficient elimination of these oxidants rather than overproduction. The antioxidant quercetin is a potential therapy that may address both the elimination of oxidants as well as regulation of metabolism in corneas with KC, considering that excessive lactate production has been associated with oxidative stress and KC.^[52-54] Future studies should focus on therapeutic agents that

can bring the ROS/RNS balance into equilibrium and reduce oxidative damage in corneas with KC.

Acknowledgments

We want to thank all of the keratoconus patients and their families for participating in this study.

Financial Support and Sponsorship

This study was supported by Schoellerman Charitable Foundation, the Discovery Eye Foundation, Departmental Unrestricted Grant from Research to Prevent Blindness, and the National Keratoconus Foundation.

Conflicts of Interest

There are no conflicts of interest.
